Objectives

- Quantify GHG (CO_2 , CH_4) fluxes vertically, from a point measurement scaled to the annual accumulation.
- Understand the drivers of GHG fluxes, including temperature, light, tide, and salinity.
- Assess the impact of anthropogenic N loading on C sequestration and net GHG emissions.

Quantifying the carbon credit: Net Ecosystem Carbon Balance (NECB = dC/dt)

$$\text{NECB} = \text{dC/dt} = \text{GPP} - \text{R} - \text{F}(\text{CH}_4) - \text{F}(\text{L})$$

↙ ↓
NEP

Methods to measure blue carbon

1. Flux: Understand the mechanism and process

Net ecosystem C balance (NECB)

$$\text{NECB} = dC/dt = \text{NEP}(\text{CO}_2) - F(\text{CH}_4) - F(\text{L})$$

$$\text{NEP} = \text{GPP} - R \text{ (chamber or eddy flux)}$$

NEP: net ecosystem production

$F(\text{CH}_4)$: CH_4 flux measured simultaneously with NEP.

$F(\text{L})$: net lateral flux

2. Stock (C): Long-term soil/sediment carbon stocks and their changes

3. Modeling

Study sites

N loading:
1-10 gN/m²/y

Waquoit Bay NERR Salt Marsh Observatory Boardwalk

Boardwalk Features

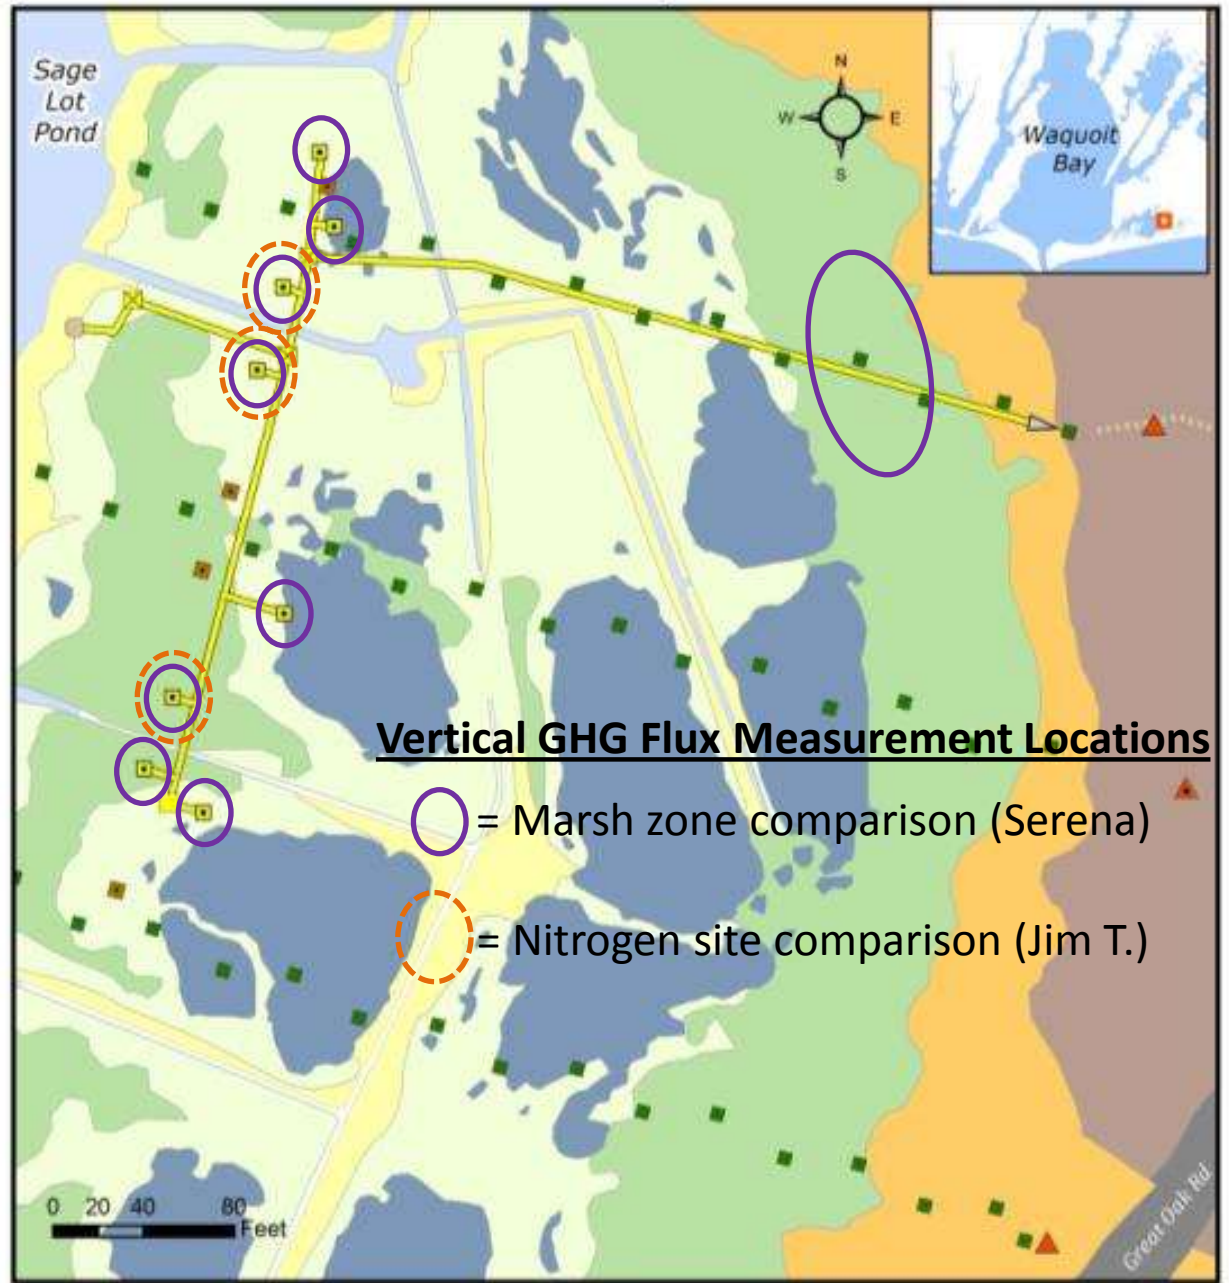

- Dock
- Endpoint
- Intersection
- Platform
- Ramp
- Walkway
- Cleared Trail

Land Cover

- Upland Forest
- Roadway
- High Marsh - High
- High Marsh - Low
- Low Marsh
- Marsh Border
- Salt Marsh Pools

Pre-existing Biomonitoring Design

- Vertical Control: Concrete Monument
- Vertical Control: Deep-driven Rod
- Surface Elevation Tables
- Vegetation Plots

We need long boardwalk

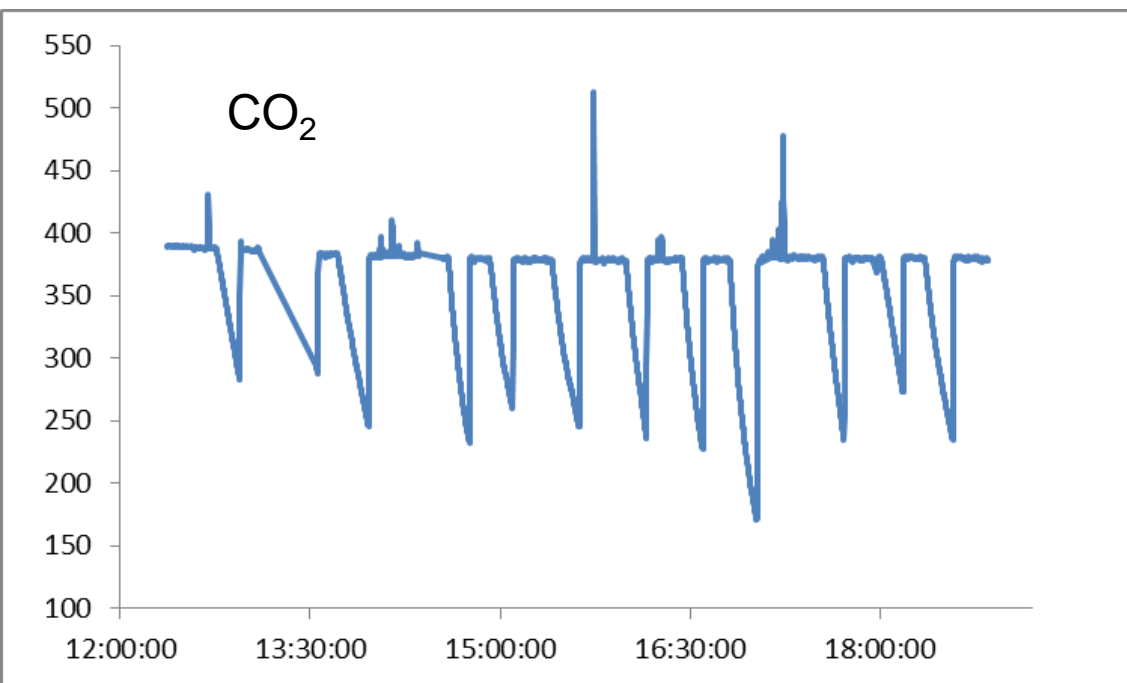

In-situ GHG flux measurement

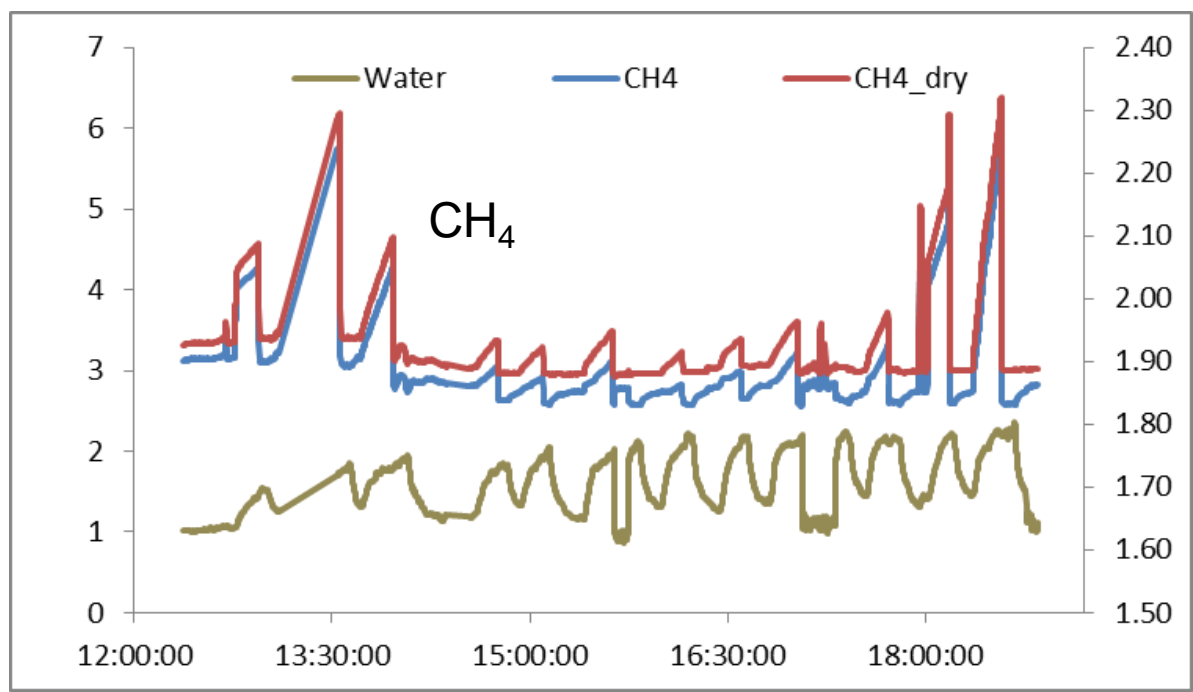

CO₂/CH₄/N₂O

**Raw data:
Gas concentration
inside the chamber**

Calculating flux from chamber measurement

$$F = \frac{dC}{dt} \frac{V}{A}$$

where C is mole concentration ($\mu\text{mol m}^{-3}$), V is volume (m^3), and A is area (m^2).

$$C = \frac{C_v P}{RT}$$

where C_v is volume concentration (ppm), P is air pressure (Pa), T is soil absolute temperature (K), and R is universal gas constant ($8.3144 \text{ J mol}^{-1} \text{ K}^{-1}$).

Therefore,

$$F = \frac{dC_v}{dt} \frac{P}{RT} \frac{V}{A}$$

CO₂ and CH₄ fluxes in the pristine site (Sage Lot)

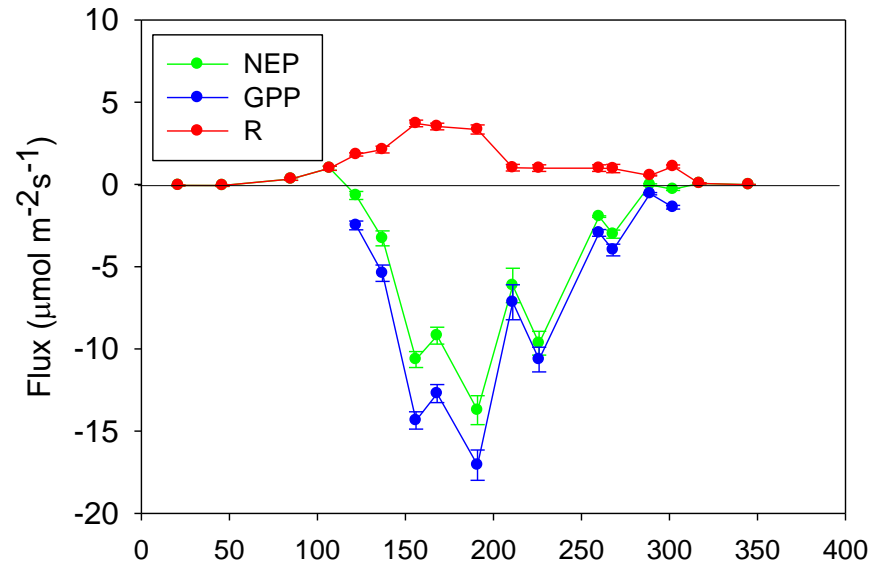

NEP = 379

CO₂ fluxes across N gradient

High N

Summary

- The salt marsh is a significant carbon sink ($\sim 160 \text{ gC m}^{-2}\text{y}^{-1}$). Restoration or conservation of this carbon sink has a significant social benefit for carbon credit.
- CH_4 fluxes are 3 orders of magnitude less than CO_2 fluxes in the salt marsh.
- Carbon fluxes are driven by light, salinity, tide, and temperature. Small amounts of N loading ($1\text{-}10 \text{ gN m}^{-2}\text{y}^{-1}$) did not change the carbon fluxes.
